# Lattices

- The set  $\Lambda = \mathbb{Z}b_1 + \mathbb{Z}b_2 + \dots + \mathbb{Z}b_n$ , where  $b_1, b_2, \dots, b_n$  are linearly independent is called a lattice.
- $\Lambda^* = \{y \in \mathbb{Z}^n : (x, y) \in \mathbb{Z}, \forall x \in \Lambda\}$
- $\text{vol}(\Lambda) = \det(b_1, b_2, \dots, b_n)$ , where  $b_1, b_2, \dots, b_n$  are the generators of  $\Lambda$ . Note that any set of generators will do since they are related by unimodular transformations.
- Let  $\Lambda$  be a lattice
  - The CVP problem is: Find  $v \in \Lambda$ :  $\|v\| = \min_{w \in \Lambda, w \neq 0} (\|w\|)$
  - The  $\text{CVP}_\gamma$  problem is: Find  $v \in \Lambda$ :  $\|v\| \leq \gamma \cdot \min_{w \in \Lambda, w \neq 0} (\|w\|)$
- Volume of  $n$ -dimensional sphere:  $V_n(r) \approx \frac{1}{\sqrt{n\pi}} \left( \sqrt{\frac{2\pi e}{n}} r \right)^n$

# Definitions

- Hermite Normal Form (HNF)

$$\begin{bmatrix} > 0 & 0 & 0 & \dots & 0 & 0 & \dots & 0 \\ \geq 0 & > 0 & 0 & 0 & 0 & 0 & \dots & 0 \\ \geq 0 & \vdots & > 0 & \ddots & \vdots & 0 & \dots & 0 \\ \geq 0 & \geq 0 & \geq 0 & \dots & 0 & 0 & \dots & 0 \\ \geq 0 & \geq 0 & \geq 0 & \dots & > 0 & 0 & \dots & 0 \end{bmatrix}$$

# Minkowski's Theorem

- Let  $\Lambda$  be a lattice in  $\mathbb{R}^n$  and suppose  $S \subseteq \mathbb{R}^n$  is a convex, centrally symmetric region. If  $\text{vol}(S) > 2^n \det(\Lambda)$  then  $S$  has a non-zero lattice point of  $\Lambda$ .

Suppose first that  $\Lambda'$  is the simple lattice generated by  $e_1, e_2, \dots, e_n$ . Represent a point  $r \in S$  as  $r = (\alpha_1 + x_1, \alpha_2 + x_2, \dots, \alpha_n + x_n)$  with  $\alpha_i \in \mathbb{Z}$  and  $|x_i| \leq 1$ , for  $1 \leq i \leq n$ . Define  $T(r) = (x_1, x_2, \dots, x_n)$ . If  $S_1 \cap S_2 = \emptyset$ ,  $\text{vol}(S_1 \cup S_2) = \text{vol}(S_1) + \text{vol}(S_2)$ . So, if  $S$  has the property that  $T(t) \neq T(s)$ ,  $\forall s \neq t \in S$ , then  $\text{vol}(S) = \text{vol}(T(S))$ . Note that  $\text{vol}(T(S)) \leq 1$ . So, if  $\text{vol}(S) > 1$ , there are at least two points  $r^{(1)} = (\alpha_1^{(1)} + x_1, \alpha_2^{(1)} + x_2, \dots, \alpha_n^{(1)} + x_n)$ ,  $r^{(2)} = (\alpha_1^{(2)} + x_1, \alpha_2^{(2)} + x_2, \dots, \alpha_n^{(2)} + x_n)$ , where  $\alpha_i^{(1)} \neq \alpha_i^{(2)}$  for some  $i$ . Since  $S$  is centrally symmetric,  $-r^{(1)}, -r^{(2)} \in S$ ; finally, note that  $0 \neq r^{(1)} - r^{(2)} \in \mathbb{Z}^n$ . Similarly, if  $\text{vol}(S) > 2^n$ , there are at least  $2^n + 1$  points  $r^{(i)}$ ,  $1 \leq i \leq 2^n + 1$  with  $0 \neq r^{(i)} - r^{(j)} \in \mathbb{Z}^n$ ,  $i \neq j$  for at least two, say  $r^{(i)}$  and  $r^{(j)}$ , all corresponding coordinates in  $r^{(i)} - T(r^{(i)})$  and  $r^{(j)} - T(r^{(j)})$  are equal (mod 2). Thus,  $0 \neq \frac{r^{(i)} - r^{(j)}}{2} \in \mathbb{Z}^n$ . But since  $S$  is convex,  $\frac{r^{(i)} - r^{(j)}}{2} \in S$ . So, the result holds for the simple lattice. Suppose now that  $\Lambda$  is generated by  $a_1, a_2, \dots, a_n$  and put  $A = [a_1, a_2, \dots, a_n]$ .  $e_i = A^{-1}(a_i)$ , so  $\text{vol}(\Lambda') = \frac{\text{vol}(\Lambda)}{\det(\Lambda)}$  and the simple lattice result thus implies the general theorem.

# q-ary lattices and other definitions

- Definition: If  $q \in \mathbb{Z}$ , a lattice,  $\Lambda$ , is called  $q$ -ary if  $q\mathbb{Z}^n \subseteq \Lambda \subseteq \mathbb{Z}^n$ .
- Suppose  $A \in \mathbb{Z}^{m \times n}$ ,  $\Lambda_q(A) = \{y \in \mathbb{Z}^n : y = A^T x \pmod{q}, x \in \mathbb{Z}_q^m\}$ .  
Note  $\Lambda_q(A)$  is  $q$ -ary.
- $\Lambda_q^\perp(A) = \{y \in \mathbb{Z}^n : Ay = 0 \pmod{q}\}$
- $\lambda_1(\Lambda) = \min_{v \in \Lambda} \|v\|$
- $\lambda_n(\Lambda) = \min_S (\max_{v \in S} \|v\|)$ , where  $S \subseteq \Lambda$  is a set of linearly independent vectors,  $|S| = n$
- Solving CVP in  $\Lambda_q^\perp(A)$  when  $A$  is chosen uniformly at random is as hard as worst case CVP.

# Some simple results

- Remember  $S$  is centrally symmetric if  $s \in S$  implies  $-s \in S$ , and  $S$  is convex if  $s, t \in S$  implies  $us + (1 - u)t \in S, u \in [0,1]$ . We used this in proving Minkowski's Theorem.
- Theorem:  $\lambda_1(\Lambda) \leq \sqrt{n} \det(\Lambda)^{\frac{1}{n}}$ 

Let  $B_r$  be a ball centered at 0 having radius  $r = \sqrt{n} \det(\Lambda)^{\frac{1}{n}}$ . Let  $(x_1, x_2, \dots, x_n)$  be the coordinates of a vector  $v$ , with respect to the basis generating the lattice  $\Lambda$ , if  $|x_i| \leq 1$  for  $1 \leq i \leq n$ ,  $v \in B_r$ . So  $-\det(\Lambda)^{\frac{1}{n}} (1, 1, \dots, 1)$  and  $\det(\Lambda)^{\frac{1}{n}} (1, 1, \dots, 1)$  as well as the line joining them are in  $B_r$  so  $\text{vol}(B_r) \geq 2^n \det(\Lambda)$  and the result follows from Minkowski's theorem.

# Reduced Basis

- $\langle v_1, v_2 \rangle$  is reduced if
  - $\|v_2\| \leq \|v_1\|$ ; and,
  - $-1/2\|v_1\|^2 \leq (v_1, v_2) \leq 1/2\|v_1\|^2$ .

# Good basis and Gram-Schmidt Orthogonalization

- Good basis for lattices are orthonormal when that is possible. If a basis,  $b_1, b_2, \dots, b_n$  for  $\Lambda$ , is orthonormal, then, for example,  $\text{vol}(\Lambda) = ||b_1|| \cdot ||b_2|| \cdot \dots \cdot ||b_n||$
- The orthogonality defect of a basis  $b_1, b_2, \dots, b_n$  is  $\frac{||b_1|| \cdot ||b_2|| \cdot \dots \cdot ||b_n||}{\det(b_1, b_2, \dots, b_n)}$
- Given a space generated by  $b_1, b_2, \dots, b_n$  can also be generated by a set of vectors,  $b_1^*, b_2^*, \dots, b_n^*$  with the property that  $(b_i^*, b_j^*) = 0, i \neq j$ . The Gram-Schmidt orthogonalization procedure computes this.

GSO, given,  $b_1, b_2, \dots, b_n$ , compute  $b_1^*, b_2^*, \dots, b_n^*$

1. put  $b_1^* = b_1$ .

2. for  $i = 2, i \leq n$

$$b_i^* = b_i - \sum_{j=1}^{i-1} \mu_{i,j} b_j, \mu_{i,j} = \frac{(b_j^*, b_i)}{(b_j^*, b_j^*)}$$

# Size Reduction

- Definition: A basis  $b_1, b_2, \dots, b_n$  is *size reduced* if  $|\mu_{i,j}| \leq \frac{1}{2}$ , in the Gram-Schmidt orthogonalization procedure.
- If  $b_1, b_2, \dots, b_n$  is a basis for  $\Lambda$ , in general,  $b_1^*, b_2^*, \dots, b_n^*$  is not also a lattice basis because  $\mu_{i,j}$  is generally not an integer. We can find a “nearly” orthogonal set of vectors  $b'_1, b'_2, \dots, b'_n$  in  $\Lambda$ , by rounding the  $\mu_{i,j}$ .  $b'_1, b'_2, \dots, b'_n$  is also a basis for the lattice and has the same gram Schmidt basis,  $b_1^*, b_2^*, \dots, b_n^*$ . When performing GSO on this *reduced* basis,  $|\mu_{i,j}| \leq \frac{1}{2}$ .

## Size-reduction

for  $i = 2, i \leq n$

for  $j = i - 1, j \geq 1$

$b_i \leftarrow b_i - \lceil \mu_{ij} \rceil b_j$

for  $k = 1, k \leq j$

$\mu_{ik} \leftarrow \mu_{ik} - \lceil \mu_{ij} \rceil \mu_{jk}$

# Size reduction and basis reordering

- Let  $b_1, b_2, \dots, b_n$  be a basis for  $\Lambda$ , and  $b_1^*, b_2^*, \dots, b_n^*$  the resulting GSO basis. Let  $B_i = ||b_i||^2$ . Then  $b_1, b_2, \dots, b_n$  satisfies the *Lovasz condition* with factor  $\delta$  if it is size reduced and  $(\delta - \mu_{i+1,i}^2)B_i \leq B_{i+1}$ . The LLL algorithm calculates such a basis.

## LLL Algorithm

Given  $b_1, b_2, \dots, b_n$  generating  $\Lambda$ , calculate the LLL reduced basis

1. Reduce the basis  $b_1, b_2, \dots, b_n$  with the size reduction algorithm and calculate  $b_1^*, b_2^*, \dots, b_n^*$  and  $\mu_{ij}$
2. Compute  $B_i = ||b_i^*||^2, i = 1, 2, \dots, n$
3. for  $i = 1, i < n$ 
  4. If  $((\delta - \mu_{i+1,i}^2)B_i > B_{i+1})$ 
    5. Swap  $b_i$  and  $b_{i+1}$
    6. Go to 1
7. return  $b_1, b_2, \dots, b_n$

# Example (LLL including GSO)

- LLL ( $\delta = \frac{3}{4}$ )
- $b_1 = (2,3,14)^T, b_2 = (0,7,11)^T, b_3 = (0,0,23)^T$ .
  - GSO:  $b_1^* = b_1, b_2^* = b_2 - \mu_{21}b_1, \mu_{21} = \frac{(b_1^*, b_2)}{(b_1^*, b_1^*)} = \frac{21+154}{4+9+196} = \frac{175}{209}, \mu_{31} = \frac{322}{209}, \mu_{31} = \frac{3473}{4905}. b_2^* = (-\frac{350}{209}, \frac{938}{209}, -\frac{151}{209})^T$
  - Size reduction:  $b_2 = b_2 - \lceil \mu_{21} \rceil b_1 = (-2,4,-3)^T, \mu_{21} = \mu_{21} - \lceil \mu_{21} \rceil = -\frac{34}{209}; b_3 = b_3 - \lceil \mu_{32} \rceil b_2 = (-2,4,20)^T, \mu_{31} = \mu_{31} - \lceil \mu_{31} \rceil = -\frac{1432}{4905};$  last change is  $b_3 = b_3 - \lceil \mu_{31} \rceil b_1 = (-4,1,6)^T, \mu_{31} = \mu_{31} - \lceil \mu_{31} \rceil = -\frac{79}{209}.$
  - Now,  $b_1 = (2,3,14)^T, b_2 = (-2,4,-3)^T, b_3 = (-4,1,6)^T$ .
  - $B_1 = 209, B_2 = \frac{4905}{209}, B_3 = \frac{103684}{4905}$ . Lovasz condition is not satisfied for  $i = 1$ : since  $(\delta - \mu_{21}^2)B_1 > B_2$ . So swap  $b_1$  and  $b_2$ .
  - Applying GSO we get  $\mu_{21} = \frac{-34}{29}, \mu_{31} = \frac{-6}{29},$  and  $\mu_{32} = \frac{2087}{4905}.$
  - Size reduction produces:  $b_2 = b_2 - \lceil \mu_{21} \rceil b_1 = (0,7,11)^T$  and  $\mu_{21} = \frac{-6}{29}.$   $\mu_{31}$  and  $\mu_{32}$  don't change.  $\mu_{32}$

# Example (LLL including GSO) - continued

- Now Lovasz condition is satisfied for  $i = 1$  since  $(\delta - \mu_{21}^2)B_1 < B_2$ . but not  $i = 2$  since  $(\delta - \mu_{32}^2)B_2 < B_3$ . swap  $b_2$  and  $b_3$ .
  - Now,  $b_1 = (-2, 4, -3)^T$ ,  $b_2 = (-4, 1, 6)^T$ ,  $b_3 = (0, 7, 11)^T$ .  $B_1 = 29$ ,  $B_2 = \frac{1501}{29}$ ,  $B_3 = \frac{103684}{1501}$ . GSO coefficients are  $\mu_{21} = \frac{-6}{29}$ ,  $\mu_{31} = \frac{-5}{29}$ , and  $\mu_{32} = \frac{2087}{1501}$ . Applying size reduction does not affect  $b_2$  or  $\mu_{21}$ .  $b_3 = b_3 - \lceil \mu_{32} \rceil b_2 = (4, 6, 5)^T$ ,  $\mu_{31} = \mu_{31} - \lceil \mu_{32} \rceil \mu_{21} = \frac{1}{29}$ ,  $\mu_{31} = \frac{586}{1501}$ . Both Lovasz conditions now hold.
  - LLL basis is thus  $b_1 = (-2, 4, -3)^T$ ,  $b_2 = (-4, 1, 6)^T$ ,  $b_3 = (4, 6, 5)^T$ . Notice  $\|b_1\|$  is actually the shortest vector in  $\Lambda$ .

# LLL Properties

- Suppose we apply LLL to  $b_1, b_2, \dots, b_n$ , with  $b_1^*, b_2^*, \dots, b_n^*$  and  $B_1, B_2, \dots, B_n$  defined as above. With  $X = \min_{v \in \Lambda} (||b_i||)$  and  $\frac{1}{4} < \delta < 1$ , LLL runs in  $O(n^6 \ln(x)^3)$ .
  - $B_i \leq ||b_i||^2 \leq (\frac{1}{2} + 2^{i-2})B_i$
  - $||b_i|| \leq 2^{\frac{i-1}{2}} ||b_i^*||$
  - $\lambda_1(\Lambda) \geq \min_i (||b_i^*||)$
  - $||b_1|| \leq 2^{\frac{n-1}{2}} \lambda_1(\Lambda)$
  - $\det(\Lambda) \leq \prod_{i=1}^n ||b_i|| \leq 2^{\frac{n(n-1)}{4}} \det(\Lambda)$
  - $||b_i|| \leq 2^{\frac{(n-1)}{4}} \det(\Lambda)^{\frac{1}{n}}$
- If  $w$  is a vector in  $\mathbb{R}^n$  and the lattice basis for  $\Lambda$  is  $b_1, b_2, \dots, b_n$  with  $B = [b_1, b_2, \dots, b_n]$ , the coefficients for  $w$  are  $u = B^{-1}(w)$ .  $w$  is not necessarily in the lattice but if we take each element in  $u$  and round it,  $B \downarrow B^{-1}(w) \in \Lambda$ . This is *Babai rounding*.

# Attack on RSA using LLL

- Attack applies to messages of the form "M xxx" where only "xxx" varies (e.g.- "The key is xxx") and xxx is small.
- From now on, assume  $M(x) = B + x$  where B is fixed
  - $|x| < Y$ .
  - Not that  $E(M(x)) = c = (B + x)^3 \pmod n$
  - $f(x) = (B+x)^3 - c = x^3 + a_2x^2 + a_1x + a_0 \pmod n$ .
- We want to find  $x$ :  $f(x) = 0 \pmod n$ , a solution to this, m, will be the corresponding plaintext.

# Attack on RSA using LLL

- To apply LLL, let:
  - $v_1 = (n, 0, 0, 0),$
  - $v_2 = (0, Yn, 0, 0),$
  - $v_3 = (0, 0, Y^2n, 0),$
  - $v_4 = (a_0, a_1Y, a_2Y^2, a_3Y^3)$
- When we apply LLL, we get a vector,  $b_1$ :
  - $||b_1|| \leq 2^{3/4} |\det(v_1, v_2, v_3, v_4)| = 2^{3/4} n^{3/4} Y^{3/2}$  .... *Equation 1.*
- Let  $b_1 = c_1v_1 + \dots + c_4v_4 = (e_0, Ye_1, Y^2e_2, Y^3e_3).$  Then:

# Attack on RSA using LLL

- Now set  $g(x) = e_3x^3 + e_2x^2 + e_1x + e_0$ .
- From the definition of the  $e_i$ ,  $c_4 f(x) = g(x) \pmod{n}$ , so if  $m$  is a solution of  $f(x) \pmod{n}$ ,  $g(m) = c_4 f(m) = 0 \pmod{n}$ .
- The trick is to regard  $g$  as being defined over the real numbers, then the solution can be calculated using an iterative solver.
- If  $Y < 2^{(7/6)}n^{(1/6)}$ ,  $|g(x)| \leq 2||b_1||$ .
- So, using the Cauchy-Schwartz inequality,  $||b_1|| \leq 2^{-1}n$ .
- Thus  $|g(x)| < n$  and  $g(x) = 0$  yielding 3 candidates for  $x$ .
- Coppersmith extended this to small solutions of polynomials of degree  $d$  using a  $d+1$  dimensional lattice by examining the monic polynomial  $f(T) = 0 \pmod{n}$  of degree  $d$  when  $|x| \leq n^{1/d}$ .

# Example attack on RSA using LLL

- $p = 757285757575769$ ,  $q = 2545724696579693$ .
- $n = 1927841055428697487157594258917$ .
- $B = 200805000114192305180009190000$ .
- $c = (B + m)^3, 0 \leq m < 100$ .
- $f(x) = (B + x)^3 - c = x^3 + a_2x^2 + a_1x + a_0 \pmod{n}$ .
  - $a_2 = 602415000342576915540027570000$
  - $a_1 = 1123549124004247469362171467964$
  - $a_0 = 587324114445679876954457927616$
  - $v_1 = (n, 0, 0, 0)$
  - $v_2 = (0, 100n, 0, 0)$
  - $v_3 = (0, 0, 10^4n, 0)$
  - $v_4 = (a_0, a_1100, a_210^4, 10^6)$

# Example attack on RSA using LLL

- Apply LLL,  $b_1 =$ 
  - $308331465484476402v_1 + 589837092377839611v_2 +$
  - $316253828707108264v_3 + (-1012071602751202635)v_4 =$
  - $(246073430665887186108474, -577816087453534232385300,$   
 $405848565585194400880000, -1012071602751202635000000)$
- $g(x) = (-1012071602751202635) t^3 + 40584856558519440088 t^2 +$   
 $(-57781608745353442323853) t + 246073430665887186108474.$
- Roots of  $g(x)$  are  $42.00000000, (-.9496 \pm 76.0796i)$
- The answer is 42.

# GGH Public Key System

- Pick  $n, M \in \mathbb{N}$  and  $\sigma$  is “small”, say  $\sigma = 4$
- Plaintext:  $\mathcal{M} = \{x: -M \leq x \leq M\}$ , Cipher-space:  $\mathcal{C} \in \mathbb{Z}^n$ .
- Gen:
  1. Choose  $B \in \mathbb{Z}^{n \times n}$  with small entries  $|B_{ij}| \leq \sigma$
  2. Check  $B$  is invertible.  $B$  is the secret key.
  3.  $H = \text{HNF}(B)$
- Enc
  1. For  $\vec{m} \in \mathcal{M}^n$ , choose  $\vec{r} \in (-\sigma, \sigma)^n$  uniformly at random
  2.  $\vec{c} = H\vec{m} + \vec{r}$
- Dec
  1. Babai round  $\vec{m} = H^{-1}B \downarrow ((B^{-1}(\vec{c}))) \uparrow$
- Works if  $\downarrow B^{-1}(r) \uparrow = 0$ .

# GGH Example

- $B = \begin{bmatrix} 2 & -3 & 1 & -4 \\ -2 & 1 & 0 & 4 \\ -1 & 3 & 2 & 1 \\ -1 & -4 & 3 & -2 \end{bmatrix}, H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 44 & 18 & 4 & 49 \end{bmatrix}$
- $B^{-1} = \frac{1}{49} \begin{bmatrix} 61 & 45 & 10 & -27 \\ -10 & -13 & 8 & -2 \\ 29 & 23 & 16 & -4 \\ 33 & 38 & 3 & -13 \end{bmatrix}, H^{-1} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \frac{-44}{49} & \frac{-18}{49} & \frac{-4}{49} & \frac{1}{49} \end{bmatrix}$
- $m = (3, -4, 1, 3)^T, r = (-1, 1, 1, -1)^T, c = Hm + r = (2, -3, 2, 210)^T$
- $B^{-1}c = \frac{1}{7}(-809, -55, -117, -396)^T, \downarrow B^{-1}c \uparrow = (-116, -8, -17, -57)^T$
- $B \downarrow B^{-1}c \uparrow = (3, -4, 1, 211)^T$
- $m = H^{-1}B \downarrow B^{-1}c \uparrow = (3, -4, 1, 3)^T$

# Learning with Errors (LWE)

- Based on solving noisy linear equations  $\text{mod } q$ . Choose  $\vec{a}_i \in \mathbb{Z}_q^n$  uniformly at random.  $\vec{s} \in \mathbb{Z}_q^n$  is a secret and  $m \geq n$  approximate equations  $\vec{a}_i \cdot \vec{s} = b_i \pmod{q}$ . Errors,  $e_1, e_2, \dots, e_n$  are chosen from distribution  $\chi$ .
- Reduces to LWE:
  - Search LWE problem: Given  $a_{ij}, (\vec{b} + \vec{e})$  find  $\vec{s}$ .
  - Decision LWE: Distinguish, with non-negligible probability, between  $\vec{b} = A\vec{s} + \vec{e}$  and  $\vec{b} \in \mathbb{Z}_q^m$  chosen uniformly at random given  $A, \vec{b}$
- Errors chosen from distribution,  $p(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp(-\frac{x^2}{2\sigma^2})$ . Often use  $s = \sigma\sqrt{2\pi}$  as parameter specifying distribution.
- Regev's showed it is possible to pick parameters so that solving an LWE cipher is equivalent to solving worst-case LWE .
  - Theorem (Regev): Let  $n \in \mathbb{N}$  be a security parameter,  $m, q \in \mathbb{N}$ , polynomial in  $n$  and  $\chi = D_{\mathbb{Z},s}$  a discrete Gaussian distribution with  $s = \alpha q > 2\sqrt{n}$ ,  $0 < \alpha < 1$ . Then solving the LWE decision problem is at least as hard as quantumly solving  $SIVP_\gamma$  on an arbitrary  $n$ -dimensional lattice where  $\gamma = \tilde{O}(n/\alpha)$ .

# LWE cryptosystem

- Given  $(n \geq m, l, t, r, q, \chi)$  where  $\chi$  is a probability distribution  $\mathbb{Z}_q$ , message space is  $\mathbb{Z}_2^l$  and cipher space is  $\mathbb{Z}_q^n \times \mathbb{Z}_q^l$ .
- Key Gen
  1. Choose  $S \in \mathbb{Z}_q^{n \times l}$ , uniformly from the distribution  $\chi$ .
  2. Choose  $A \in \mathbb{Z}_q^{m \times n}$ , and  $E \in \mathbb{Z}_q^{m \times l}$  uniformly from the distribution  $\chi$ .
  3. Private key is  $S$ , public key is  $(A, P = AS + E)$
- Enc
  1. For  $\vec{v} \in \mathbb{Z}_2^l$ , choose  $\vec{a} \in \{0,1\}^m$ , uniformly at random
  2.  $\vec{CT} = (\vec{u} = A^T \vec{a}, \vec{c} = P^T \vec{a} + \uparrow \frac{q}{2} \downarrow \vec{v})$
- Dec
  1. Compute  $\uparrow (\uparrow \frac{q}{2} \downarrow)^{-1} (\vec{c} - S^T \vec{u}) \uparrow \pmod{2}$
- Decryption may have errors. Suppose  $\chi$  is a discrete Gaussian  $D_{\mathbb{Z},s}$ . Then  $E^T \vec{a}$  has magnitude  $\leq \sqrt{m}s$  with high probability. Error occurs if  $E^T \vec{a} \geq \frac{q}{4}$ . One can show that for any  $n, \exists q, m, s$  such that the error is small and the underlying LWE problem is hard.

# LWE example

- $n = 4, q = 23, m = 8, \alpha = \frac{5}{23}, s = 5, \sigma = \frac{s}{\sqrt{2\pi}}, l = 4$

- $A^{m \times n} = A = \begin{bmatrix} 9 & 5 & 11 & 13 \\ 13 & 6 & 6 & 2 \\ 6 & 21 & 17 & 18 \\ 22 & 19 & 20 & 8 \\ 2 & 17 & 10 & 21 \\ 10 & 8 & 17 & 11 \\ 5 & 16 & 12 & 2 \\ 5 & 7 & 11 & 7 \end{bmatrix}, S^{n \times l} = S = \begin{bmatrix} 5 & 2 & 9 & 1 \\ 6 & 8 & 19 & 1 \\ 19 & 18 & 9 & 18 \\ 9 & 2 & 14 & 18 \end{bmatrix}$

# LWE example

$$\bullet \quad E^{m \times l} = E = \begin{bmatrix} 0 & 22 & 1 & 21 \\ 0 & 22 & 22 & 22 \\ 6 & 21 & 17 & 18 \\ 22 & 22 & 22 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 \\ 1 & 22 & 1 & 22 \\ 22 & 0 & 0 & 1 \end{bmatrix}, P^{m \times l} = P = \begin{bmatrix} 10 & 5 & 21 & 7 \\ 3 & 1 & 13 & 1 \\ 19 & 15 & 6 & 13 \\ 22 & 22 & 22 & 0 \\ 9 & 20 & 20 & 17 \\ 15 & 21 & 1 & 2 \\ 0 & 12 & 3 & 19 \\ 16 & 2 & 7 & 15 \end{bmatrix},$$

# LWE example

- Encrypt  $\vec{v} = (1,0,1,1)^T$ , using  $a = (1,1,0,1,0,0,0,1)^T$ 
  - $\downarrow \frac{23}{2} \vec{v} \uparrow = (12,0,12,12)^T$ ,
  - $(u, c) = \left( A^T a, P^T a + \downarrow \frac{23}{2} m \uparrow \right) = ((3,14,2,7)^T, (4,5,7,5)^T) \pmod{23}$
- Decrypt:
  - $\vec{v}' = c - S^T u = (11,21,12,10)^T \pmod{23}$ ,
  - $\downarrow \frac{1}{12} \vec{v}' \uparrow \pmod{2} = (1,0,1,1)^T$

# LWE example

- Encrypt  $m = (1,0,1,1)^T$ , using  $a = (1,1,0,1,0,0,0,1)^T$ 
  - $\lfloor \frac{23}{2} m \rfloor = (12,0,12,12)^T$ ,
  - $(u, c) = \left( A^T a, P^T a + \lfloor \frac{23}{2} m \rfloor \right) = ((3,14,2,7)^T, (4,5,7,5)^T) \pmod{23}$
- Decrypt:
  - $m' = c - S^T u = (11,21,12,10)^T \pmod{23}$ ,
  - $\lfloor \frac{1}{12} m' \rfloor \pmod{2} = (1,0,1,1)^T$

From Heiko Knopse

# LWE/Ring-LWE parameters

Level	n	q	s	P	P&A	c	Exp
Low	128	4093	8.87	$2.9 \times 10^5$	$7.4 \times 10^5$	$3.8 \times 10^3$	30
High	320	4093	8	$4.9 \times 10^5$	$17.7 \times 10^5$	$17.4 \times 10^3$	42

- Ring-LWE cuts ciphertext by factor of n

# Ring-LWE

- Put  $R = R_{n,q} = \frac{\mathbb{Z}_q[x]}{x^{n+1}+1}$ ,  $n = 2^k$ ,  $R \approx \mathbb{Z}_q^n$ .  $a \in R$ , generates ideal  $(a)$  corresponding to a  $q$ -ary ideal lattice.
- Ring LWE: Given  $a \in R$ , and  $b = as + e$ , for  $s, e \in R$ , find  $s$ .
- Solving R-LWE is at least as hard as solving  $CVP_\gamma$  on arbitrary ideal lattices

# NTRU Public Key System

- NTRU is a ring lattice-based system.
- $R = \frac{\mathbb{Z}[x]}{x^N - 1}$ ,  $R_p = \frac{\mathbb{Z}_p[x]}{x^N - 1}$ ,  $R_q = \frac{\mathbb{Z}_q[x]}{x^N - 1}$
- $(c_0 + c_1x + \cdots + c_{N-1}) = (a_0 + a_1x + \cdots + a_{N-1}) \otimes (b_0 + b_1x + \cdots + b_{N-1})$ , where  $c_k = \sum_{i+j=k \pmod N} a_i b_j$
- $\mathcal{T}(d_1, d_2)$  is the set of “ternary” polynomials of degree  $< N$ , having  $d_1$  coefficients equal to 1, having  $d_2$  coefficients equal to  $-1$ , and remaining coefficients equal to 0.
- Pick  $N, p$  prime and  $q, d \in \mathbb{N}$ ,  $(p, q) = (N, q) = 1$ ,  $q > (6d + 1)p$ .

# NTRU Public Key System

- KeyGen
  1. Pick  $f, g \in R, f \in \mathcal{T}(d+1, d), g \in \mathcal{T}(d, d)$ .
  2. Find  $f_p, f_q: f \cdot f_p = 1 \pmod{p}, f \cdot f_q = 1 \pmod{q}, h = f_q \cdot g \pmod{q}$ .
  3. Public key is  $(N, p, q, h)$ , private key is  $f$ .
- Plaintext is  $m \in R_p$ , ciphertext is  $c \in R_q$
- Encryption
  1. Chose random  $r \in R, r \in \mathcal{T}(d, d)$ .
  2.  $c = prh + m \pmod{q}$ .
- Decryption
  1. Compute  $a = fc \pmod{q}$
  2. Plaintext is  $f_p a$ .
  3. Verify that  $a = fc = f(prh + m) \pmod{q} = pfrf_qg + fm \pmod{q} = prg + fm \pmod{q}$ .

# NTRU Example

- $N = 5, p = 3, q = 29, d = 1, f = x^4 + x^3 - 1, g = x^3 - x^2$
- $f_p = -x^3 - x^2 + x - 1, f_q = -5x^4 + 8x^3 + 3x^2 + 11x + 13$
- $h = f_q g = 8x^4 + 2x^3 + 11x^2 + 13x - 5 \pmod{29}$
- $r = x^4 - x$
- $c = prh + m = 8x^4 + 21x^3 + 25x^2 + 20x + 15 \pmod{29}$
- $a = fc = -2x^4 + 2x^3 + 4x^2 - 3x + 1 \pmod{29}$
- We check  $a = prg + fm$  in  $R$
- $m = x^3 + x$

**Winner:** Dilithium (signing), Kyber (key-encapsulation)

# Common features of Dilithium and Kyber

- Ring is  $\mathbb{Z}_p[x]/(x^{256} + 1)$  in both cases
  - $p = 3329$  for Kyber
  - $p = 2^{23} - 2^{13} + 1 = 8380417$  for Dilithium
  - So, the same modular arithmetic we all grew up with.
- For  $p = 3329$ , there is a primitive (and hence 128 primitive) 256<sup>th</sup> roots of unity (You are not expected to understand this).
  - As a result,  $x^{256} + 1$  factors into coprime 128 quadratics
  - Allows us to perform a “Number Theory Transform” that turns convolution into pointwise multiplication for ring operations giving a nice speedup
- For  $p = 8380417$ , there is a primitive (and hence 256 primitive) 512<sup>th</sup> roots of unity
  - As a result,  $x^{256} + 1$  factors into coprime 256 linear polys
  - Allows us to perform a “Number Theory Transform” that turns convolution into pointwise multiplication for ring operations giving a nice speedup

# Useful definitions

- $r^+ = r \pmod{q}, q > r^+ \geq 0$
- $r' = r \pmod{\pm}(m)$  means  $r' = r \pmod{m}$  and  $-\frac{m}{2} \leq r' \leq \frac{m}{2}$ , if  $m$  is even;  
 $-\frac{m}{2} < r' \leq \frac{m}{2}$ , if  $m$  is odd
- $decompose(r, \alpha, q)$ 
  - $r_0 = r^+ \pmod{\pm}(\alpha)$
  - if  $r^+ - r_0 == (q - 1)$ 
    - $r_1 = 0, r_0 = q - 1$
  - else
    - $r_1 = \frac{r^+ - r_0}{\alpha}$
  - return  $(r_1, r_0)$

# Useful definitions

- $lowbits(x, \alpha, q)$ 
  - $(r_1, r_0) = decompose(x, \alpha, q)$
  - return  $r_0$
- $highbits(x, \alpha, q)$ 
  - $(r_1, r_0) = decompose(x, \alpha, q)$
  - return  $r_1$
- $power2round(r, d, q)$ 
  - $r^+ = r \bmod(q)$
  - $r_0 = r^+ \bmod^{\pm}(2^d)$
  - return  $(\frac{r^+ - r_0}{2^d}, r_0)$

# Examples

- $decompose(r, \alpha, q)$  examples (second shows roundoff edge case)

$q$	$\alpha$	$r$	$r \bmod^{\pm}(\alpha)$	$r - r \bmod^{\pm}(\alpha)$	$r_0$	$r_1$
17	8	5	-3	8	-3	1
17	8	15	-1	16	-2	0
3329	104	50	50	0	50	0
3329	104	100	-4	104	-4	1

# SHAKE-256/SHAKE-128

- $H(v, d) = \text{SHAKE256}(v, d)$
- $H_{128}(v, d) = \text{SHAKE128}(v, d)$
- $\text{RAWSHAKE256}(J, d) = \text{KECCAK}[512](J||11, d)$
- $\text{SHAKE256}(M, d) = \text{RAWSHAKE256}(M||11, d)$
- $\text{RAWSHAKE128}(J, d) = \text{KECCAK}[256](J||11, d)$
- $\text{SHAKE128}(M, d) = \text{RAWSHAKE128}(M||11, d)$
- Note
  - $\text{SHA3}_{256}(M) = \text{KECCAK}[512](M||11, 256)$
  - $\text{SHA3}_{512}(M) = \text{KECCAK}[1024](M||11, 1024)$

# Number Theory Transform (NTT)

- $p = 3329, p - 1 = 2^8 \cdot 13$ .
- $\mathbb{Z}_p$  has a primitive 256<sup>th</sup> root of unity ( $\zeta = 17$  is a primitive root) but no 512 root of unity, so  $x^{256} + 1$  factors into 128 coprime quadratic factors of the form  $(x^2 - \xi)$ ,  $17^{128} = -1$ .
- $x^{256} + 1 = \prod_{k=0}^{127} (x^2 - \zeta^{2 \cdot \text{bitrev}_7(k)+1})$ .
- $\text{bitrev}_7(k)$  reverses the bit order in a 7-bit byte,  $k$ .
  - $x^{256} + 1 = (x^2 - 17) \cdot (x^2 - 17^{129}) \cdot \dots \cdot (x^2 - 17^{255})$
- For  $p = 8380417$ ,  $\zeta = 1753$  is a primitive 512<sup>th</sup> root of unity,
  - $p - 1 = 2^{13}(2^{10} - 1) = 2^{13} \cdot 3 \cdot 11 \cdot 31$ .
- Because of this, an analog of the Chinese remainder theorem holds in
$$R_p = \frac{\mathbb{Z}_p(x)}{x^{256} + 1}.$$

# NTT for Dilithium

- $NTT: R_p \rightarrow T_p, f \mapsto \hat{f}, T_q = \prod_{i=0}^{255} \mathbb{Z}_q$
- For  $f \in R_p$ 
  - $\hat{f} = \prod_{i=0}^{511} f(\text{mod } x - \zeta^{2i+1}), \zeta = 1753$ , so each element in the vector is just an element of  $\mathbb{Z}_p$
  - If  $a(x) = a_0 + a_1x + a_2x^2 + \dots + a_{511}x^{255}$
  - $\hat{a} = (a(r_0), a(-r_0), \dots, a(r_{127}), a(-r_{127})), r_i = \zeta^{i+128}$
- Multiplication is then pointwise

# Dilithium template

- Gen
  - $A \leftarrow R_q^{k \times l}$
  - $(s_1, s_2) \leftarrow S_\eta^l \times S_\eta^k$
  - $t = As_1 + s_2$
  - return  $(pk = (A, t), sk = (A, t, s_1, s_2))$
- Verify( $pk, M, \sigma = (z, c)$ )
  - $w'_1 = \text{highbits}(Az - ct, 2\gamma_2)$
  - return  $\|z\|_\infty < \gamma_1 - \beta \wedge c == H(M || w'_1)$
- Sign( $sk, m$ )
  - $z = \perp$
  - while  $z == \perp$ 
    - $y \leftarrow S_{\gamma_1-1}^l$
    - $w_1 = \text{highbits}(Ay, 2\gamma_2)$
    - $c \in B_{60}, c = H(M || w_1)$
    - // view  $c$  as polynomial in  $R_q$
    - $z = y + cs_1$
    - if  $\|z\|_\infty < \gamma_1 - \beta \vee \|\text{lowbits}(Ay - cs_2, 2\gamma_2)\|_\infty \geq \gamma_2 - \beta$ 
      - $z = \perp$
  - return  $\sigma = (z, c)$

For real Dilithium,  $k = 5, l = 4$

# Dilithium security argument -1

$$\eta = 5, \gamma_1 = \frac{q-1}{16}, \gamma_2 = \frac{\gamma_1}{2}, R_q = \frac{\mathbb{Z}_q[x]}{x^{256}+1}, q = 2^{23} - 2^{13} + 1,$$

$$q - 1 = 2^{13} \cdot 3 \cdot 11 \cdot 31. k = 5, l = 4$$

1.  $A \leftarrow R_q^{k \times l}, (s_1, s_2) \leftarrow S_\eta^l \times S_\eta^k, t = As_1 + s_2, pk = (A, t), sk = (A, t, s_1, s_2), S = R_q$
2.  $y \leftarrow S_{\gamma_1-1}^l, w_1 = \text{highbits}_{2\gamma_2}(Ay)$ 
  - Write coefficients of  $w = Ay$ , as  $w^{[i]} = (2\gamma_1)w_1^{[i]} + w_0^{[i]}$
  - $w_1 = \text{highbits}_{2\gamma_2}(Ay)$  then  $w_0^{[i]} < \gamma_2$
3.  $c \in B_{60}, c = H(M || w_1)$ . Set  $\beta = \max_i((cs_1)^{[i]})$ . Then  $\beta \leq 60\eta$ .
4. Set  $z = y + cs_1$ , if any coefficient of  $z > \gamma_1 - \beta$ , reject and start over.
5. If any coefficient of  $\text{lowbits}_{2\gamma_2}(Az - ct) > \gamma_2 - \beta$ , reject and start over.
  - Note:  $Az - ct = Ay - cs_2$
  - coefficients of  $z \leq \gamma_1 - \beta$ , coefficients of  $\text{lowbits}_{2\gamma_2}(Az - ct) \leq \gamma_2 - \beta$
6. Signature is  $\sigma = (z, c)$ 
  - $c \in B_{60}$  is ensured by SampleInBall in the final algorithm.
  - Parameters chosen so that expected rejections in steps 4 and 5 is between 4 and 7.

# Dilithium security argument - 2

## Verification

- $A\mathbf{z} - c\mathbf{t} = A\mathbf{y} - c\mathbf{s}_2$
- To show  $highbits_{2\gamma_2}(A\mathbf{z} - c\mathbf{t}) = highbits_{2\gamma_2}(A\mathbf{y})$ , we need only show  $highbits_{2\gamma_2}(A\mathbf{y}) = highbits_{2\gamma_2}(A\mathbf{y} - c\mathbf{s}_2)$ .
  - This follows because  $|lowbits_{2\gamma_2}(A\mathbf{y} - c\mathbf{s}_2)|_\infty < \gamma_2 - \beta$ ; and,
  - The coefficients of  $\|c\mathbf{s}_2\|_\infty < \beta$
  - Adding  $c\mathbf{s}_2$  never causes a carry of  $\gamma_2$  from the lowbits and, hence,  $highbits_{2\gamma_2}(A\mathbf{z} - c\mathbf{t}) = highbits_{2\gamma_2}(A\mathbf{y})$
  - Now we can compute  $highbits_{2\gamma_2}(\mathbf{w}_1)$  and hence  $H(M||\mathbf{w}_1)$

# Template $\rightarrow$ Dilithium

- NTT is used to speed multiplications.
- Produce hint,  $h$  to help verifier calculate  $w'_1$  in verify.
  - $r_1 \leftarrow \text{Highbits}(r), v \leftarrow \text{Highbits}(r + z), h \leftarrow [[r_1 \neq v]]$
  - $h \leftarrow \text{MakeHint}(- \ll (ct_0) \gg, w - \ll cs_2 \gg + \ll ct_0 \gg)$
  - $\tilde{c} \leftarrow H(\mu || w_1, \lambda)$
- Drop  $d = 13$ , bottom bits in  $t$ .  $\omega = 75$  is man number of 1's in  $h$ .
- In final algorithm,  $A$ , is generated from a seed using SHAKE-128.
- Notes:
  - Compute  $w'_1 = \text{highbits}_{2\gamma_2}(Az - ct)$  from the compressed public key.
  - SampleinBall, guarantees  $c \in B_{60}$  using Fisher-Yates shuffle on  $H(M || w_1)$

# Template → Dilithium

- $\xi \leftarrow H(\{0,1\}^{256}), (\rho, \rho', K) \leftarrow H(\xi, 512), \hat{A} \leftarrow \text{Expand}(\rho)$
- $tr \leftarrow H(pk, 512), \text{sign: } \mu \leftarrow H(tr || M, 512), (\hat{s}_1, \hat{s}_2) \leftarrow \text{ExpandS}(\rho').$
- $(t_1, t_0) \leftarrow \text{Power2Round}(t, d), sk \leftarrow (\rho, K, tr, s_1, s_2, t_0)$
- $\text{Usehint}(h, w'_{\text{appx}}), r, z \in \mathbb{Z}_q$ 
  - $m \leftarrow \frac{q-1}{2\gamma_2}, (r_1, r_0) \leftarrow \text{decompose}(r)$
  - If  $(h == 1 \wedge r_0 > 0)$  return  $(r_1 + 1) \bmod m$
  - If  $(h == 1 \wedge r_0 \leq 0)$  return  $(r_1 - 1) \bmod m$
  - return  $r_1$

Algorithm	Public key	Private key size	Signature size
ML-DSA-87	4864	2592	4595

# Dilithium, unedited, motivation

- Basic scheme is Fiat-Shamir MSA-DL with aborts.
- Classic version with discrete log is:
  - Prover and verifier know  $(g, y = g^x)$ . Prover knows  $x$ .
    1. Prover generates  $r$ , sends commitment  $g^r$ .
    2. Verifier sends  $c$ .
    3. Prover returns  $s = r - cx$ .
    4. Verifier can check  $g^s \cdot y^c = g^r$
- Non interactive version replaces  $c$  with hash of  $g^r || M$
- LWE version
  - Publish  $A, t = As_1 + s_2$
  - Prover: Pick,  $y$ , commit by sending  $w_{approx} = Ay + y_2$ ,  $y_2$  has small coefficients.
  - Verifier: Send challenge,  $c$ .
  - Prover:  $z = y + cs_1$
  - Verifier: Check  $z$  and  $Az - tc \approx w_{approx}$

# Dilithium (simplified)

- Remember  $A^{k \times l}$  is generated randomly from  $R = \mathbb{Z}_p[x]/(x^{256} + 1)$ .
- $s_1$  is a vector of dimension  $l$  with entries from  $R$  has random coefficients  $\leq \eta$
- $s_2$  is a vector of dimension  $k$  with entries from  $R$  has random coefficients  $\leq \eta$
- $t = As_1 + s_2$

Sign

```
y := S $\gamma_1 - 1$ l  
w1 := highbits(Ay, 2 $\gamma_2$ )  
c := SH(M || w1)  
z := y + cs1  
return (z, c)
```

Verify

```
w1' := highbits(Az - ct, 2 $\gamma_2$ )  
c' := SH(M || w1')  
Check c' == c AND ||z|| $\infty$  <  
 $\gamma_1 - \beta$ 
```

# Dilithium (less simplified)

**Parameters:**  $p = 8380417$ ,  $k = 5$ ,  $l = 4$ ,  $\gamma_1 = \frac{p-1}{16}$ ,  $\gamma_2 = \frac{\gamma_1}{2}$ ,  $\eta = 5$ ,  $\beta = 275$

$$R_p = \frac{\mathbb{Z}_p[x]}{x^{256}+1}$$

- **KeyGen**

- $A \in R_p^{k \times l}$ , selected from random distribution over  $R_p$
- $(s_1, s_2) \in S_\eta^k \times S_\eta^l$ , selected at random,  $S_\eta^k$  consists of elements of  $R_p^k$  with coefficients  $\leq \eta$
- Set  $t = As_1 + s_2$
- Public key is  $(A, t)$ , Private key is  $(s_1, s_2)$

For the sake of compression  $A$  is generated from a seed and SHAKE-256

# Dilithium

- $\text{Sign}(\text{pk}, \text{sk}, M)$  --- simplified

1.  $z = \perp$
2. **while** ( $z = \perp$ ) {
3.    $y = S_{\gamma_1}^l - 1$
4.    $w_1 = \text{highbits}(Ay, 2\gamma_2)$
5.    $c = \text{SHAKE} - 256(M || w_1)$
6.    $z = y + cs_2$
7.   **if** ( $||z||_\infty \geq \gamma_1 - \beta$ ) **OR**  $\text{lowbits}(Ay - cs_2, 2\gamma_1) \geq \gamma_2 - \beta$ ) **then**  $z = \perp$
8. }

Signature is  $(z, c)$

- Real Dilithium uses a number of functions to generate  $A$  from a seed. It also has a hedged version and a deterministic version. The hedged version avoids some possible side channels.

# Dilithium

- $\text{Verify}(\text{pk}, M, z, c)$  --- simplified
  1.  $w'_1 = \text{highbits}(Az - ct, 2\gamma_2)$
  2. Return true if  $\|z\|_\infty \leq \gamma_1 - \beta$  AND  $c = \text{SHAKE} - 256(M \| w'_1)$ , otherwise return false

# Useful definitions

- $usehint(h, r)$

# Dilithium, unedited, motivation

- Preliminary lattice version is prover generates:  $A \in \mathbb{Z}_q^{k \times l}$ ,  $S_1 \in \mathbb{Z}_q^{l \times n}$ ,  $S_2 \in \mathbb{Z}_q^{k \times n}$ , with short coefficients and computes  $t = AS_1 + S_2$ . Public key is  $(A, t)$ . Private key is  $(S_1, S_2)$ 
  1. Prover generates  $y \in \mathbb{Z}_q^l$  with “small coefficients”. Sends commitment as  $Ay$
  2. Verifiers sends challenge  $c \in \mathbb{Z}_q^n$  with small coefficients
  3. Prover returns  $z = y + S_1c$ .
  4. Verifier checks coefficients of  $z$  are small and that  $Az - tc \approx Ay$
- To avoid having  $z$  leak  $S_1$ , signer applies rejection sampling to  $z$ .
- Dilithium
  1. Uses elements of  $R_q = \frac{\mathbb{Z}_q[x]}{x^{256}+1}$  rather than  $\mathbb{Z}_q$ .
  2. Uses a seed,  $\rho$ , to generate  $A$ , compresses  $t$  by dropping low order bits.
  3. Signs a message representative,  $\mu$ , which is a hash of the public key and the message
  4. Uses a rounded version of  $w = Ay$ ,  $w_1$ .
  5. Provides a hint,  $h$ , to help reconstruct  $w_1$  from  $z$

# Dilithium parameters for security category 5

Parameter	Meaning	Value
$q$	modulus	8380417
$d$	# dropped bits from $t$	13
$\tau$	# $\pm 1$ s in $c(x)$	60
$\lambda$	Collision strength	256
$\gamma_1$	Coefficient range of $y$	$2^{19}$
$\gamma_2$	Low order rounding range	$\frac{q-1}{32}$
$(k, l)$	Dimensions of $A$	(8,7)
$\eta$	Private key range	2
$\beta = \tau \cdot \eta$		120
$\omega$	Max # of 1's in hint	75

# Kyber

- Kyber is a key encapsulation algorithm that uses a public key encryption algorithm similar to Dilithium in conjunction with an encapsulation mechanism (Fujisaki-Okamoto transform) which converts a conditionally secure encryption into a CCA safe encapsulation. Here are some definitions.
  - $PRF_{\eta}(s, b) = \text{shake256}(s || b, 64 \cdot \eta)$
  - $XOF(\rho, i, j) = \text{shake128}(\rho || i || j)$
  - $H(s) = \text{sha3}_{256}(s)$ ,  $J(s) = \text{shake256}_{32}(s)$
  - $G(s) = \text{sha3}_{512}(s)$
  - $NTT$  and  $NTT^{-1}$  are different for Kyber and Dilithium
- Fujisaki-Okamoto transform:
  - $\mathcal{E}_{pk}^{hy}(m) = \mathcal{E}_{pk}^{asym}(\sigma, H(\sigma, m)) || \mathcal{E}_{G(\sigma)}^{sym}(m)$
  - $\sigma$  is random string,  $G, H$  are hash functions,  $\mathcal{E}_{G(\sigma)}^{sym}$  is symmetric encryption with key  $G(\sigma)$  and  $\mathcal{E}_{pk}^{asym}$  is original asymmetric encryption algorithm.

# Attacks

The Blum-Kalai-Wasserman (BKW) algorithm is a combinatorial algorithm used to solve the Learning With Errors (LWE).

The attack typically involves two main phases:

**Reduction Phase:** This phase progressively reduces the dimension of the LWE/LWR problem, essentially trying to simplify the equations involved. This is achieved by combining samples (vectors with associated 'noise' or errors) in a way that eliminates certain positions in the vectors, albeit at the cost of increasing the noise in the remaining positions.

**Solving Phase:** Once the problem is reduced to a manageable size, the remaining entries of the secret are recovered. This often involves techniques like hypothesis testing to distinguish the correct guess of the secret sub-vector from incorrect ones.

End

# LLL Theorem

- Let  $L$  be the  $n$ -dimensional lattice generated by  $\langle v_1, \dots, v_n \rangle$  and  $\lambda_1$  the length of the shortest vector in  $L$ . The LLL algorithm produces a reduced basis  $\langle b_1, \dots, b_n \rangle$  of  $L$ .
  1.  $\|b_1\| \leq 2^{(n-1)/4} D^{1/n}$ .
  2.  $\|b_1\| \leq 2^{(n-1)/2} \lambda_1$ .
  3.  $\|b_1\| \|b_2\| \dots \|b_n\| \leq 2^{n(n-1)/4} D$ .
- If  $\|b_i\|^2 \leq C$  algorithm takes  $O(n^4 \lg(C))$ .

# Gauss again

- Let  $\langle v_1, v_2 \rangle$  be a basis for a two-dimensional lattice  $L$  in  $\mathbb{R}^2$ . The following algorithm produces a reduced basis.

```
for(;;) {  
    if(||v1|| > ||v2||)  
        swap v1 and v2;  
    t = [(v1, v2) / (v1, v1)]; // [] is the "closest  
        integer" function  
    if(t == 0)  
        return;  
    v2 = v2 - tv1;  
}
```

- $\langle v_1, v_2 \rangle$  is now a reduced basis and  $v_1$  is a shortest vector in the lattice.
